

Angular Signals vs RxJS

When Should You Use What?

What Are Signals?

Signals are Angular's new reactive state primitives that store a value and notify the UI whenever that value changes.

What Are Signals?

- No subscriptions needed
- Purely synchronous
- Perfect for UI-level state
- Lightweight and easy to reason about

When to Use Signals?

Use Signals when your requirement is:

- ✓ Local component state management
- ✓ UI-driven changes
- ✓ Simple read/write reactive updates
- ✓ Synchronous and predictable behavior

What Is RxJS?

RxJS is a powerful reactive programming library based on Observables that handles asynchronous and event-driven data streams.

Key Points:

- Best for async operations
- Works with streams (events, API data, intervals)
- Uses operators like switchMap, debounceTime, mergeMap
- Perfect for complex workflows

When to Use RxJS?

Use RxJS when your use case involves:

- ✓ API calls and async data
- ✓ Data streams (scrolls, clicks, timers)
- ✓ Debounce/throttle logic
- ✓ switchMap/mergeMap pipelines
- ✓ Complex multi-step async workflows
