

DATA BINDING IN ANGULAR

codewithrutu_09

Data binding is a technique, where the **data stays in sync** between the component and the view.

Whenever the user updates the data in the view, Angular updates the component. When the component gets new data, the Angular updates the view.

Data Binding can be either:

One way binding or Two-way binding

ONE WAY DATA BINDING

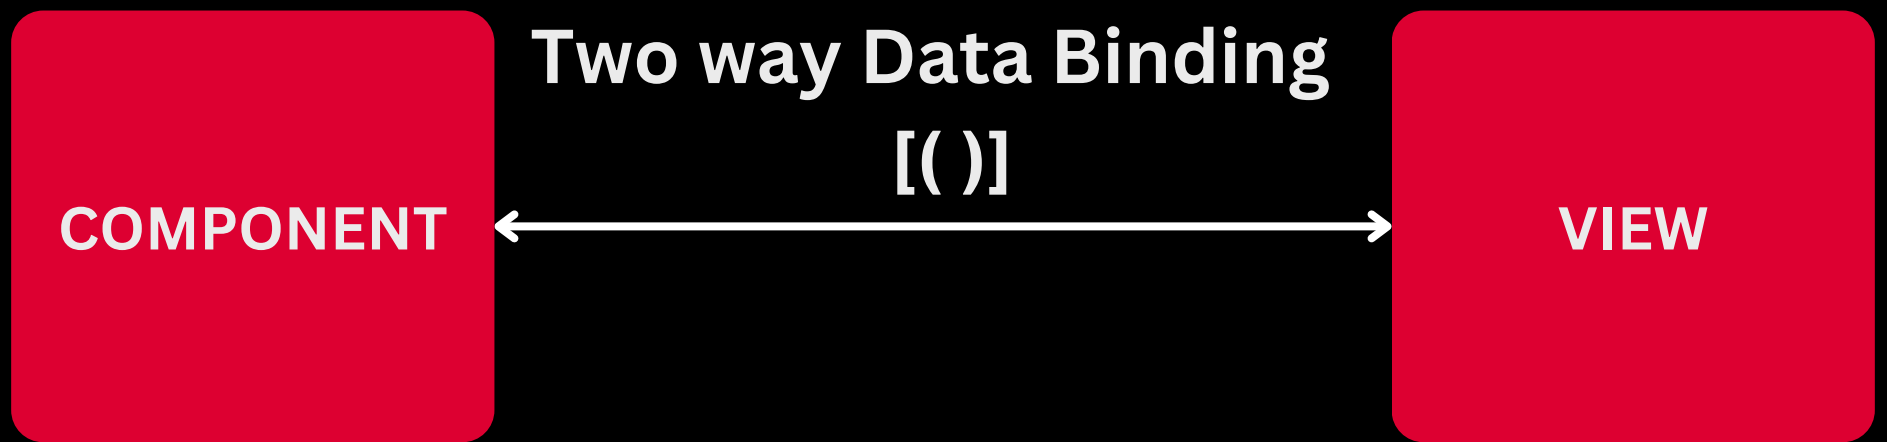

In one way binding **data flows from one direction**. Either from view to component or from component to view.

TWO WAY DATA BINDING

Two-way binding means changes made in **component data should sync to the view** so any changes made in the view are immediately updated in the respective component data.

Two-way binding is used mainly in **data entry forms** whenever user makes any changes in the data we would like to update our model in the component with new data and if model changes, we would like to update view as well.

Angular uses combination of properly binding and event binding by using **ngModel** directive

```
<input type="text" [(ngModel)]= "firstName" />
```

The above syntax sets up both property binding & event binding

We will cover **One**
way data binding and
Two way Data
Binding in more
